Gradually the Cheyenne, moving intermittently by bead or village groupings, moved in a generally westward direction, probably as a result of pressure from other tribes moving away from regions of white actilement. In this carliest known period the Cheyenne vere probably forest hunters living in houses of wiching type similar to those of the Sadt and The move westward was up the Minnesote River, a tributary of the Fox. Mississippi, and thence to the drainage of the Red River of the North in castern North Dakota. In the Red River erea the Cheyenne practiced a mined economy of horticulture and hunting, and lived in permanent villages in houses of the earth lodge type. One inportant exchaeological site generally agreed to be early Cheyenne is located on a tributery of the Led liver near Lisbon, South Dakota, and is dated at about 1750. This site, called the Sheyanne-Cheyanne Site, was an earth louge village protected on three sides by a deep unbastioned ditch, and on the other side by the river bank. The earth lodges averaged about forty feet in director, and were structurally similar to those constructed by the Mandon, Hidatsa and Arikara tribes whose villages were located on the upper Missouri River. Cheyenne pottery from this site shows rescublances both to Microwi River wares, and to certain wares in Minnesota. Bone implements were found in abundance and included agricultural and hide dressing tools. The importance of hunting in the econony was indicated by the great abount of unimal bone refuse found. Materials of European origin included iron and brass knife blades and glass beads, but there were no horse bones or other evidence of the horse. This site is interesting in that it indicates that in the mid-eighteenth, contury the Cheyenne were still a pedestrian people living in relatively permanent villages and practicing some horticulture. However only a half-century later travellers described them as fully equestrian nomade of the Plains.
